While you're there, also look for and install the **Adafruit\_ZeroDMA** library.

The Adafruit\_GFX library always works together with an *additional* library unique to each specific display type; for example, the ST7735 1.8" color LCD requires installing Adafruit\_GFX, Adafruit\_ZeroDMA *and* the Adafruit\_ST7735 library. The following libraries now operate in this manner:

- [Link: https://github.com/adafruit/RGB-matrix-Panel](https://github.com/adafruit/RGB-matrix-Panel) RGBmatrixPanel, for our [16x32](http://www.adafruit.com/products/420) and [32x32](http://www.adafruit.com/products/607) RGB LED matrix panels.
- [Link: https://github.com/adafruit/TFTLCD-Library](https://github.com/adafruit/TFTLCD-Library) Adafruit\_TFTLCD, for our 2.8" [TFT LCD touchscreen breakout](http://www.adafruit.com/products/335) and [TFT Touch Shield for Arduino](http://www.adafruit.com/products/376).
- [Adafruit\\_HX8340B](https://github.com/adafruit/Adafruit-HX8340B), for our [2.2" TFT Display with microSD](http://www.adafruit.com/products/797).
- [Adafruit\\_ST7735](https://github.com/adafruit/Adafruit-ST7735-Library), for our [1.8" TFT Display with microSD](http://www.adafruit.com/products/358).
- [Adafruit\\_PCD8544](https://github.com/adafruit/Adafruit-PCD8544-Nokia-5110-LCD-library), for the [Nokia 5110/3310 monochrome LCD](http://www.adafruit.com/products/338).
- [Adafruit-Graphic-VFD-Display-Library](https://github.com/adafruit/Adafruit-Graphic-VFD-Display-Library), for our [128x64 Graphic VFD](https://www.adafruit.com/products/773).
- [Adafruit-SSD1331-OLED-Driver-Library-for-Arduino](https://github.com/adafruit/Adafruit-SSD1331-OLED-Driver-Library-for-Arduino) for the [0.96" 16-bit Color OLED w/microSD Holder](http://www.adafruit.com/products/684).
- [Adafruit\\_SSD1306](https://github.com/adafruit/Adafruit_SSD1306) for the Monochrome [128x64](https://www.adafruit.com/products/326) and [128x32](https://www.adafruit.com/products/661) OLEDs.

The libraries are written in C++ for Arduino but could easily be ported to any microcontroller by rewriting the low-level pin access functions.

Older versions of the Arduino IDE software require installing libraries manually; the Arduino Library Manager did not yet exist. If using an early version of the Arduino software, this might be a good time to upgrade. Otherwise, [this tutorial](http://learn.adafruit.com/arduino-tips-tricks-and-techniques/arduino-libraries) explains how to install and use Arduino libraries. Here are links to download the GFX and ZeroDMA libraries directly (use the links above to get the corresponding display-specific libraries):

[Download Adafruit\\_GFX Library](https://github.com/adafruit/Adafruit-GFX-Library/archive/master.zip)

[Download Adafruit\\_ZeroDMA Library](https://github.com/adafruit/Adafruit_ZeroDMA/archive/master.zip)

Pixels & picture elements, the blocks comprising a digital image; are addressed by their

horizontal (X) and vertical (Y) coordinates. The coordinate system places the origin (0,0) at the top left corner, with positive X increasing to the right and positive Y increasing downward. This is upside-down relative to the standard Cartesian coordinate system of mathematics, but is established practice in many computer graphics systems (a throwback to the days of raster-scan CRT graphics, which worked top-to-bottom). To use a tall &#8220;portrait&#8221; layout rather than wide

&#8220;landscape&#8221; format, or if physical constraints dictate the orientation of a display in an enclosure, one of four rotation settings can also be applied, indicating which corner of the display represents the top left.

Also unlike the mathematical Cartesian coordinate system, points here have dimension &#8212; they are always one full integer pixel wide and tall.

src="https://cdn-learn.adafruit.com/assets/assets/000/001/264/medium800/lcds\_\_\_displays\_coordsys.png?1396770439" alt="lcds\_displays\_coordsys.png"/>

Coordinates are always expressed in pixel units; there is no implicit scale to a real-world measure like millimeters or inches, and the size of a displayed graphic will be a function of that specific display's dot pitch or pixel density. If you're aiming for a real-world dimension, you'll need to scale your coordinates to suit. Dot pitch can often be found in the device datasheet, or by measuring the screen width and dividing the number of pixels across by this measurement.

For color-capable displays, colors are represented as unsigned 16-bit values. Some displays may physically be capable of more or fewer bits than this, but the library operates with 16-bit values; these are easy for the Arduino to work with while also providing a consistent data type across all the different displays. The primary color components &#8212; red, green and blue &#8212; are all &#8220;packed&#8221; into a single 16-bit variable, with the most significant 5 bits conveying red, middle 6 bits conveying green, and least significant 5 bits conveying blue. That extra bit is assigned to green because our eyes are most sensitive to green light.

Science!

[https://cdn-learn.adafruit.com/assets/assets/000/001/265/medium800/lcds\\_\\_\\_displays\\_colorpack.png?1396770449](https://cdn-learn.adafruit.com/assets/assets/000/001/265/medium800/lcds___displays_colorpack.png?1396770449) 800w,

[https://cdn-learn.adafruit.com/assets/assets/000/001/265/large1024/lcds\\_\\_\\_displays\\_colorpack.png?1396770449](https://cdn-learn.adafruit.com/assets/assets/000/001/265/large1024/lcds___displays_colorpack.png?1396770449) 1024w" sizes="(max-width: 768px) 100vw, (max-width: 1024px) 65vw, (max-width: 1365px) 47vw, 750px,

src="https://cdn-learn.adafruit.com/assets/assets/000/001/265/medium800/lcds\_\_\_displays\_colorpack.png?1396770449" alt="lcds\_displays\_colorpack.png"/>

For the most common primary and secondary colors, we have this handy cheat-sheet that you can include in your own code. Of course, you can pick any of 65,536 different colors, but this basic list may be easiest when starting out:

```
Color definitions #define BLACK 0x0000
```

```
#define BLUE 0x001F #define RED 0xF800 #define GREEN 0x07E0 #define CYAN 0x07FF #define MAGENTA 0xF81F #define YELLOW 0xFFE0 #define WHITE 0xFFFF
```

Color definitions

```
#define BLACK 0x0000 #define BLUE 0x001F #define RED 0xF800 #define GREEN 0x07E0 #define CYAN 0x07FF #define MAGENTA 0xF81F #define YELLOW 0xFFE0 #define WHITE 0xFFFF
```

For monochrome (single-color) displays, colors are always specified as simply `set` or `clear`. The semantics of `set/clear` are specific to the type of display: with something like a luminous OLED display, a `set` pixel is lighted, whereas with a reflective LCD display, a `set` pixel is typically dark. There may be exceptions, but generally you can count on `clear` representing the default background state for a freshly-initialized display, whatever that works out to be.

Each device-specific display library will have its own constructors and initialization functions. These are documented in the individual tutorials for each display type, or oftentimes are evident in the specific library header file. The remainder of this tutorial covers the common graphics functions that work the same regardless of the display type. The function descriptions below are merely `prototypes`; there's an assumption that a display object is declared and initialized as needed by the device-specific library. Look at the example code with each library to see it in actual use. For example, where we show `print(1234.56)`, your actual code would place the object name before this, e.g. it might `readScreen.print(1234.56)`; (if you have declared your display object with the name `screen`).

First up is the most basic pixel pusher. You can call this with X, Y coordinates and a color and it will make a single dot:

```
void drawPixel(uint16_t x, uint16_t y, uint16_t color);
```

```
void drawPixel(uint16_t x, uint16_t y, uint16_t color);
```

<https://learn.adafruit.com/assets/1267>  `srcset="https://cdn-learn.adafruit.com/assets/assets/000/001/267/medium260/lcds__displays_st7735pixel.jpg?1396770465 260w, https://cdn-learn.adafruit.com/assets/assets/000/001/267/medium640/lcds__displays_st7735pixel.jpg?1396770465 640w, https://cdn-learn.adafruit.com/assets/assets/000/001/267/medium800/lcds__displays_st7735pixel.jpg?1396770465 800w, https://cdn-learn.adafruit.com/assets/assets/000/001/267/large1024/lcds__displays_st7735pixel.jpg?1396770465 1024w"` sizes="(max-width: 768px) 100vw, (max-width: 1024px) 65vw, (max-width: 1365px) 47vw, 750px," `src="https://cdn-learn.adafruit.com/assets/assets/000/001/267/medium800/lcds__displays_st7735pixel.jpg?1396770465"` alt="lcds\_displays\_st7735pixel.jpg"/>

You can also draw lines, with a starting and end point and color:

```
void drawLine(uint16_t x0, uint16_t y0, uint16_t x1, uint16_t y1, uint16_t color);
```

```
void drawLine(uint16_t x0, uint16_t y0, uint16_t x1, uint16_t y1, uint16_t color);
```

<https://learn.adafruit.com/assets/1268>  `srcset="https://cdn-learn.adafruit.com/assets/assets/000/001/268/medium260/lcds__displays_line.png?1396770476 260w, https://cdn-learn.adafruit.com/assets/assets/000/001/268/medium640/lcds__displays_line.png?1396770476 640w, https://cdn-learn.adafruit.com/assets/assets/000/001/268/medium800/lcds__displays_line.png?1396770476 800w"`

src=„[https://cdn-learn.adafruit.com/assets/assets/000/001/276/medium800/lcds\\_\\_\\_displays\\_char.png?1396770557](https://cdn-learn.adafruit.com/assets/assets/000/001/276/medium800/lcds___displays_char.png?1396770557)“ alt=„lcds\_displays\_char.png“/></a></div> <div class=„row-fluid build-text“ readability=„38“> <p>Text is very flexible but operates a bit differently. Instead of one procedure, the text size, color and position are set up in separate functions and then the print() function is used &#8212; this makes it easy and provides all of the same string and number formatting capabilities of the familiar Serial.print() function!</p> </div> <div class=„build-code code-element“ readability=„13“> <pre class=„code-text-only c4“>void setCursor(uint16\_t x0, uint16\_t y0); void setTextColor(uint16\_t color); void setTextColor(uint16\_t color, uint16\_t backgroundColor); void setTextSize(uint8\_t size); void setTextWrap(boolean w);</pre> <pre class=„prettyprint linenums“>void setCursor(uint16\_t x0, uint16\_t y0); void setTextColor(uint16\_t color); void setTextColor(uint16\_t color, uint16\_t backgroundColor); void setTextSize(uint8\_t size); void setTextWrap(boolean w);</pre></div> <div class=„row-fluid build-text“ readability=„45“> <p>Begin with&#160;setCursor(x, y), which will place the top left corner of the text wherever you please. Initially this is set to (0,0) (the top-left corner of the screen). Then set the text color with&#160;setTextColor(color)&#160;&#8212; by default this is white. Text is normally drawn &#8220;clear&#8221; &#8212; the open parts of each character show the original background contents, but if you want the text to block out what&#8217;s underneath, a background color can be specified as an optional second parameter to setTextColor(). Finally,&#160;setTextSize(size)&#160;will multiply the scale of the text by a given integer factor. Below you can see scales of 1 (the default), 2 and 3. It appears blocky at larger sizes because we only ship the library with a single simple font, to save space.</p> </div> <p>Note that the text background color is not supported for custom fonts. For these, you will need to determine the text extents and explicitly draw a filled rectangle before drawing the text.</p> <div class=„row-fluid build-image“><a href=„<https://learn.adafruit.com/assets/1277>“><img class=„1277-asset img-responsive“ srcset=„[https://cdn-learn.adafruit.com/assets/assets/000/001/277/medium260/lcds\\_\\_\\_displays\\_text.jpg?1396770564](https://cdn-learn.adafruit.com/assets/assets/000/001/277/medium260/lcds___displays_text.jpg?1396770564) 260w, [https://cdn-learn.adafruit.com/assets/assets/000/001/277/medium640/lcds\\_\\_\\_displays\\_text.jpg?1396770564](https://cdn-learn.adafruit.com/assets/assets/000/001/277/medium640/lcds___displays_text.jpg?1396770564) 640w, [https://cdn-learn.adafruit.com/assets/assets/000/001/277/medium800/lcds\\_\\_\\_displays\\_text.jpg?1396770564](https://cdn-learn.adafruit.com/assets/assets/000/001/277/medium800/lcds___displays_text.jpg?1396770564) 800w, [https://cdn-learn.adafruit.com/assets/assets/000/001/277/large1024/lcds\\_\\_\\_displays\\_text.jpg?1396770564](https://cdn-learn.adafruit.com/assets/assets/000/001/277/large1024/lcds___displays_text.jpg?1396770564) 1024w“ sizes="(max-width: 768px) 100vw, (max-width: 1024px) 65vw, (max-width: 1365px) 47vw, 750px,, src=„[https://cdn-learn.adafruit.com/assets/assets/000/001/277/medium800/lcds\\_\\_\\_displays\\_text.jpg?1396770564](https://cdn-learn.adafruit.com/assets/assets/000/001/277/medium800/lcds___displays_text.jpg?1396770564)“ alt=„lcds\_displays\_text.jpg“/></a></div> <div class=„row-fluid build-text“ readability=„50“> <p>After setting everything up, you can use&#160;print()&#160;or&#160;println()&#160;&#8212; just like you do with Serial printing!</em>&#160;For example, to print a string, use&#160;print(„Hello world“)&#160;- that&#8217;s the first line of the image above. You can also use&#160;print()&#160;for numbers and variables &#8212; the second line above is the output of print(1234.56)&#160;and the third line is&#160;print(0xDEADBEEF, HEX).</p> <p>By default, long lines of text are set to automatically &#8220;wrap&#8221; back to the leftmost column. To override this behavior (so text will run off the

right side of the display &#8212; useful for scrolling marquee effects), use `setTextWrap(false)`. The normal wrapping behavior is restored with `setTextWrap(true)`.

See the [Using Fonts](https://learn.adafruit.com/adafruit-gfx-graphics-library/using-fonts) page for additional text features in the latest GFX library.

You can draw small monochrome (single color) bitmaps, good for sprites and other mini-animations or icons:

```
void drawBitmap(int16_t x, int16_t y, uint8_t *bitmap, int16_t w, int16_t h, uint16_t color);
```

```
void drawBitmap(int16_t x, int16_t y, uint8_t *bitmap, int16_t w, int16_t h, uint16_t color);
```

This issues a contiguous block of bits to the display, where each '1' bit sets the corresponding pixel to 'color,' while each '0' bit is skipped. x, y is the top-left corner where the bitmap is drawn, w, h are the width and height in pixels.

The bitmap data *must* be located in program memory using the `PROGMEM` directive. This is a somewhat advanced function and beginners are best advised to come back to this later. For an introduction, see the [Arduino tutorial on PROGMEM usage](http://arduino.cc/en/Reference/PROGMEM).

Here's a handy webtool for generating bitmap -& memorymaps

The `fillScreen()` function will set the entire display to a given color, erasing any existing content:

```
void fillScreen(uint16_t color);
```

```
void fillScreen(uint16_t color);
```

You can also rotate your drawing. Note that this will *not* rotate what you already drew, but it will change the coordinate system for any new drawing. This can be really handy if you had to turn your board or display sideways or upside down to fit in a particular enclosure. In most cases this only needs to be done once, inside `setup()`.

We can only rotate 0, 90, 180 or 270 degrees - anything else is not possible in hardware and is too taxing for an Arduino to calculate in software

800w,

[!\[\]\(d5186cb9fb9816c8537cb9f1f2a8cfab\_img.jpg\)](https://cdn-learn.adafruit.com/assets/assets/000/001/266/large1024/lcds___displays_rotated.jpg?1396770456)

1024w" sizes="(max-width: 768px) 100vw, (max-width: 1024px) 65vw, (max-width: 1365px) 47vw, 750px,"

src="https://cdn-learn.adafruit.com/assets/assets/000/001/266/medium800/lcds\_\_\_displays\_rotated.jpg?1396770456" alt="lcds\_displays\_rotated.jpg"/>

```
void setRotation(uint8_t rotation);
```

```
void setRotation(uint8_t rotation);
```

The rotation parameter can be 0, 1, 2 or 3. For displays that are part of an Arduino shield, rotation value 0 sets the display to a *portrait* (tall) mode, with the USB jack at the top right. Rotation value 2 is also a portrait mode, with the USB jack at the bottom left. Rotation 1 is *landscape* (wide) mode, with the USB jack at the bottom right, while rotation 3 is also landscape, but with the USB jack at the top left.

For other displays, please try all 4 rotations to figure out how they end up rotating as the alignment will vary depending on each display, in general the rotations move counter-clockwise

When rotating, the origin point (0,0) changes &#8212; the idea is that it should be arranged at the top-left of the display for the other graphics functions to make consistent sense (and match all the function descriptions above).

If you need to reference the size of the screen (which will change between portrait

and landscape modes), use width() and height().

```
uint16_t width(); uint16_t height();
```

```
uint16_t width(); uint16_t height();
```

Each returns the dimension (in pixels) of the corresponding axis, adjusted for the display's current rotation setting.

More recent versions of the Adafruit GFX library offer the ability to use alternate fonts besides the one standard fixed-size and -spaced face that's built in. Several alternate fonts are included, plus there's the ability to add new ones.

|                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Printed on 2025/08/02 11:59

```
FreeSansBold9pt7b.h FreeSerifItalic9pt7b.h
```

Each filename starts with the face name (FreeMono, FreeMono, FreeSerif, etc.) followed by the style (Bold, Oblique, none, etc.), font size in points (currently 9, 12, 18 and 24 point sizes are provided) and 7b to indicate that these contain 7-bit characters (ASCII codes through ~); 8-bit fonts (supporting symbols and/or international characters) are not yet provided but may come later.

After #including the Adafruit\_GFX and display-specific libraries, include the font file(s) you plan to use in your sketch. For example:

```
#include <Adafruit_GFX.h>
Core graphics library #include <Adafruit_TFTLCD.h>
Hardware-specific library #include <Fonts/FreeMonoBoldOblique12pt7b.h>
#include <Fonts/FreeSerif9pt7b.h>
#include <Adafruit_GFX.h>
Core graphics library #include <Adafruit_TFTLCD.h>
Hardware-specific library #include <Fonts/FreeMonoBoldOblique12pt7b.h>
#include <Fonts/FreeSerif9pt7b.h>
```

Each font takes up a bit of program space; larger fonts typically require more room. This is a finite resource (about 32K max on an Arduino Uno for font data and all of your sketch code), so choose carefully. Too big and the code will refuse to compile (or in some edge cases, may compile but then won't upload to the board). If this happens, use fewer or smaller fonts, or use the standard built-in font.

Inside these .h files are several data structures, including one main font structure which will usually have the same name as the font file (minus the .h). To select a font for subsequent graphics operations, use the setFont() function, passing the address of this structure, such as:

```
tft.setFont(&FreeMonoBoldOblique12pt7b);
```

Subsequent calls to tft.print() will now use this font. Most other attributes that previously worked with the built-in font (color, size, etc.) work similarly here.

To return to the standard fixed-size font, call setFont(), passing either NULL or no arguments:

```
tft.setFont();
```

Some text attributes behave a little differently with these new fonts. Not wanting to break compatibility with existing code, the classic font continues to behave as before.

For example, whereas the cursor position when printing with the classic font identified the top-left corner of the character cell, with new fonts the cursor position indicates the baseline & the bottom-most row of subsequent text. Characters may vary in size and width, and don't necessarily begin at the exact cursor column (as in below, this character starts one pixel left of the cursor, but others may be on or to the right of it).

When switching between built-in and custom fonts, the library will automatically shift the cursor position up or down 6 pixels as needed to continue along the same baseline.

src=„[https://cdn-learn.adafruit.com/assets/assets/000/029/277/medium800/lcds\\_\\_\\_displays\\_NewChar.png?1450831047](https://cdn-learn.adafruit.com/assets/assets/000/029/277/medium800/lcds___displays_NewChar.png?1450831047)“ alt=„lcds\_\_\_displays\_NewChar.png“/></a></div> <div class=„row-fluid build-text“ readability=„46“> <p>One &#8220;gotcha&#8221; to be aware of with new fonts: there is no &#8220;background&#8221; color option&#8230;you can set this value but it will be ignored. This is on purpose and by design.</p> <p>The background color feature has typically been used with the &#8220;classic&#8221; font to overwrite old screen contents with new data. This only works because those characters are a uniform size; it&#8217;s not a sensible thing to do with proportionally-spaced fonts with characters of varying sizes (and which may overlap).</p> <p>To replace previously-drawn text when using a custom font, use the getTextBounds() function to determine the smallest rectangle encompassing a string, erase the area using fillRect(), then draw new text.</p> </div> <div class=„build-code code-element“ readability=„23“> <pre class=„code-text-only c4“>int16\_t x1, y1; uint16\_t w, h; tft.getTextBounds(string, x, y, &amp;x1, &amp;y1, &amp;w, &amp;h);</pre> <pre class=„prettyprint linenums“>int16\_t x1, y1; uint16\_t w, h; tft.getTextBounds(string, x, y, &amp;x1, &amp;y1, &amp;w, &amp;h);</pre></div> <div class=„row-fluid build-text“ readability=„42“> <p>getTextBounds expects a string, a starting cursor X&amp;Y position (the current cursor position will not be altered), and addresses of two signed and two unsigned 16-bit integers. These last four values will then contain the upper-left corner and the width &amp; height of the area covered by this text &#8212; these can then be passed directly as arguments to fillRect().</p> <p>This will unfortunately &#8220;blink&#8221; the text when erasing and redrawing, but is unavoidable. The old scheme of drawing background pixels in the same pass only creates a new set of problems.</p> </div> <div class=„row-fluid build-text“ readability=„43“> <p>If you want to create new font sizes not included with the library, or adapt entirely new fonts, we have a command-line tool&#160;(in the &#8220;fontconvert&#8221; folder) for this. It should work on many Linux- or UNIX-like systems (Raspberry Pi, Mac OS X, maybe Cygwin for Windows, among others).</p> <p>Building this tool requires the gcc compiler and <a href=„http://www.freetype.org“>FreeType</a>&#160;library. Most Linux distributions include both by default. For others, you may need to install developer tools and download and <a href=„http://download.savannah.gnu.org/releases/freetype/“>build FreeType from the source</a>. Then edit the Makefile to match your setup before invoking &#8220;make&#8221;.</p> </div> <div class=„row-fluid build-text“ readability=„38“> <p><em>fontconvert</em> expects at least two arguments: a font filename (such as a scalable TrueType vector font) and a size, in points (72 points = 1 inch; the code presumes a screen resolution similar to the Adafruit 2.8“ TFT displays). The output should be redirected to a .h file&#8230;you can call this whatever you like but I try to be somewhat descriptive:</p> </div> <div class=„build-code code-element“ readability=„7“> <pre class=„code-text-only c4“>./fontconvert myfont.ttf 12 &gt; myfont12pt7b.h</pre> <pre class=„prettyprint linenums“>./fontconvert myfont.ttf 12 &gt; myfont12pt7b.h</pre></div> <div class=„row-fluid build-text“ readability=„45“> <p>The GNU FreeFont files are not included in the library repository <a href=„http://savannah.gnu.org/projects/freefont/“>but are easily&#160;downloaded</a>. Or you can convert most any font you like.</p> <p><strong>The name assigned to the font structure within&#160;this file is based on the <em>input</em> filename and font size, not the output.</strong> This is why I recommend using descriptive filenames incorporating the font base name, size, and „7p“. Then the .h&#160;filename and font structure name can match.</p> <p>The resulting .h file can be copied to the Adafruit\_GFX/Fonts folder, or you can import the file as a new tab in your Arduino sketch using the Sketch&#8594;Add File&#8230; command.</p> <p>If in the Fonts folder, use this syntax when #including the file:</p> </div> <div class=„build-code code-element“ readability=„7“> <pre class=„code-text-only c4“>#include &lt;Fonts/myfont12pt7b.h&gt;</pre>

```

<p>That’s “imageread,” not “ermahgerd.”</p> </div> <div
class=„row-fluid build-text“ readability=„37“> <p>The syntax for using this library (and the separate
installation above) are admittedly a bit peculiar…it’s a side-effect
of the way Arduino handles libraries. We purposefully did not roll this into Adafruit_GFX
because any mere mention of the SD library will incur all of that
library’s considerable memory requirements…even if one’s sketch
doesn’t use an SD card at all! A majority of graphics projects are self-contained
and don’t reference files from a card…not everybody needs this functionality.</p>
</div> <div class=„row-fluid build-text“ readability=„34“> <p>There are several example
sketches in the Adafruit_ImageReader/examples folder. You can dissect these for ideas how
to use the library in your own projects.</p> <p>They all start with several #includes…</p>

Above we see it being used with the Adafruit\_ILI9341 display library required of certain shields, FeatherWings or breakout boards. Others examples reference Adafruit\_HX8357, Adafruit\_ST7735, or other color TFT or OLED display libraries&#8230;use the right one for the hardware you have.</p> <p>We declare a display object (called &#8220;tft&#8221; in most of the examples) the usual way&#8230;for example, with the 2.8 inch TFT touch shield for Arduino, it’s</p> </div> <div class=„build-code code-element“ readability=„13“> <pre class=„code-text-only c4“>#define SD\_CS 4 SD card select pin #define TFT\_CS 10 TFT select pin #define TFT\_DC 9 TFT display/command pin Adafruit\_ILI9341 tft = Adafruit\_ILI9341(TFT\_CS, TFT\_DC);</pre> <pre class=„prettyprint linenums“>#define SD\_CS 4 SD card select pin #define TFT\_CS 10 TFT select pin #define TFT\_DC 9 TFT display/command pin Adafruit\_ILI9341 tft = Adafruit\_ILI9341(TFT\_CS, TFT\_DC);</pre></div> <div class=„row-fluid build-text“ readability=„33“> <p>And then also declare a global Adafruit\_ImageReader object&#8230;we&#8217;ll call it &#8220;reader.&#8221; This will be used to access the image-loading functions later:</p> </div> <div class=„build-code code-element“ readability=„7“> <pre class=„code-text-only c4“>Adafruit\_ImageReader reader; Class w/image-reading functions</pre> <pre class=„prettyprint linenums“>Adafruit\_ImageReader reader; Class w/image-reading functions</pre></div> <div class=„row-fluid build-text“ readability=„35“> <p>After the SD and TFT’s

begin()

functions have been called (see the example sketches, in the

setup()

function), you can then call

reader.drawBMP()

to load a BMP image from the card to the screen:</p> </div> <div class=„build-code code-element“ readability=„13“> <pre class=„code-text-only c4“>ImageReturnCode stat; stat = reader.drawBMP(„/purple.bmp“, tft, 0, 0);</pre> <pre class=„prettyprint linenums“>ImageReturnCode stat; stat = reader.drawBMP(„/purple.bmp“, tft, 0, 0);</pre></div> <div class=„row-fluid build-text“ readability=„39“> <p>This accepts <strong>four</strong> arguments:</p> <ul><li>A filename in &#8220;8.3&#8221; format (you shouldn’t need to provide an absolute path (the leading &#8220;/&#8221;), but there are some issues with the SD library on some cutting-edge boards like the ESP32, so go ahead and include this for good measure).</li> <li>The display object where the image will be drawn (e.g. &#8220;tft&#8221;). <em>This is the weird syntax previously mentioned&#8230;rather than tft.drawBMP(), it’s reader.drawBMP(tft), because reasons.</em></li> <li>An X and Y coordinate where the top-left corner of the image is positioned (this doesn’t need to be within screen bounds&#8230;the library will clip the image as it’s loaded). 0, 0 will draw the image at the top-left corner&#8230;so if the image dimensions match the screen dimensions, it will fill the entire screen.</li> </ul><p>This function returns a value of type

## ImageReturnCode

, which you can either ignore or use it to provide some diagnostic functionality. Possible values are:

### IMAGE\_SUCCESS

Image loaded successfully (or was clipped fully off screen, still considered successful; in that there was no error).

### IMAGE\_ERR\_FILE\_NOT\_FOUND

Could not open the requested file (check spelling, confirm file actually exists on the card, make sure it conforms to 8.3 file naming convention (e.g. filename.bmp)).

### IMAGE\_ERR\_FORMAT

Not a supported image format. Currently only **uncompressed 24-bit color BMPs** are supported (more will likely be added over time).

### IMAGE\_ERR\_MALLOC

Could not allocate memory for operation (drawBMP() won't generate this error, but other ImageReader functions might).

Rather than dealing with these values yourself, you can optionally call a function to display a basic diagnostic message to the Serial console:

```
reader.printStatus(stat);
```

```
reader.printStatus(stat);
```

If you need to know the **size** of a BMP image *without actually loading it*, there's the

### bmpDimensions()

function:

```
int32_t width, height; stat = reader.bmpDimensions("/parrot.bmp", &width, &height);
```

```
int32_t width, height; stat = reader.bmpDimensions("/parrot.bmp", &width, &height);
```

This accepts **three** arguments:

- A filename, same rules as the

### drawBMP()

function.

- Pointers** to two **32-bit integers**. On successful completion, their contents will be set to the image width and height in pixels. On any error these values should be ignored (they're left uninitialized).

This function returns an

## ImageReturnCode

as explained with the

## drawBMP ( )

function above.

Depending on image size and other factors, loading an image from SD card to screen may take several seconds. Small images;those that can fit entirely in RAM;can be loaded once and used repeatedly. This can be handy for frequently-used icons or sprites, as it's usually much easier than converting and embedding an image as an array directly in one's code;a horrible process.

This introduces another ImageReader function plus a new object type,

## Adafruit\_Image

```
Adafruit_Image img; stat = reader.loadBMP(„/wales.bmp“, img);
```

```
Adafruit_Image img; stat = reader.loadBMP(„/wales.bmp“, img);
```

## loadBMP ( )

accepts two arguments:

- A filename, same rules as the previous functions.
- An

## Adafruit\_Image

object. This is a slightly more flexible type than the bitmaps used by a few drawing functions in the GFX library.

This returns an

## ImageReturnCode

as previously described. If an image is too large to fit in available RAM, a value of

## IMAGE\_ERR\_MALLOC

will be returned. Color images require two bytes per pixel;for example, a 100×25 pixel image would need 100\*25\*2 = 5,000 bytes RAM.

On success, the

## img

object will contain the image in RAM.

The

## loadBMP ( )

function is useful only on microcontrollers with considerable RAM, like the Adafruit M0; and M4; boards, or ESP32. Small devices like the Arduino Uno just can't cut it. It might be marginally useful on the Arduino Mega with very small images.

After loading, use the

```
img.draw()
```

function to display an image on the screen:

```
img.draw(tft, x, y);
```

This accepts **three** arguments:

- A display object (e.g. `tft`; in most of the examples), similar to how

```
drawBMP()
```

worked.

- An X and Y coordinate for the upper-left corner of the image on the screen, again similar to

```
drawBMP()
```

We use

```
img.draw(tft,…);
```

rather than

```
tft.drawRGBBitmap(…);
```

(or other bitmap-drawing functions in the Adafruit\_GFX library) because in the future we plan to add more flexibility with regard to image file formats and types. The

### Adafruit\_Image

object understands a bit about the image that's been loaded and will call the appropriate bitmap-rendering function automatically, you won't have to handle each separate case on your own.

If the image failed to load for any reason,

```
img.draw()
```

can still be called, it just won't *do* anything. But at least the sketch won't crash.
